

Syntax:

variable_name = value

Example 1: Integer variable

```
In [ ]: age = 25 # Here age is variable and 25 is value
```

Example 2: String variable

```
In [1]: name = 'Alice' # name is variable and stored string 'Alice'  
print(name)
```

Alice

Example 3: Flaot variable

```
In [3]: price = 19.99 # Here price is variable and storing a flaoting- point value (number)  
print(price)
```

19.99

Example 4: Boolean variable

```
In [6]: is_active = True # Here is_active is variable and storing a boolean value  
print(is_active)
```

True

1. Sorting and Printing variable

```
In [3]: X=10 # Variable X stores the values as 10  
  
print(X) # Priting the variable X displays the value 10
```

10

2. Using variables in Expressions

```
In [1]: # Assigning variables to value  
  
a=5  
b=3  
# adding 2 variables and sorting result as 'result'  
result= a+b  
# printing the result  
  
print (result)
```

3 Changing the value of variable

```
In [4]: score = 50 # Initial value
        print (score) # output is 50

        # Changing the value of score
        score = 100
        print (score) # output is 100
```

50
100

4. Concatenating Strings

```
In [6]: # Assigning value to variable

        first_name = 'John'
        last_name = 'Doe'

        # Concatenating the variable first_name and last_name as 'full_name'

        full_name = first_name + " " + last_name

        print(full_name)
```

John Doe

5. Using Variable in Calculation

```
In [7]: # Assigning values to variables
        length = 10
        width = 5

        # Calculating the area of rectangle

        area = length * width
        print(area)
```

50

Reassigning values to variables

Python allows you to assign new value to variable anytime

```
In [10]: x = 10 # initial value assigned to variable
         print(x) # output is 10

         # Reassigning value to variable as 20

         x = 20
         print(x) # New value is 20
```

10
20

In []:
